The ongoing fragmentation of work has resulted in a narrowing of tasks into smaller pieces that can be sent outside the organization and, in many instances, around the world. This trend is shifting the boundaries of organizations and leading to increased outsourcing. Though the consolidation of volume may lead to productivity improvement, little is known about how this shift toward outsourcing influences learning by providers of outsourced services. When producing output, the content of the knowledge gained can vary from one unit to the next. One dimension along which output can vary—a dimension with particular relevance in outsourcing—is the end customer for whom it is produced. The performance benefits of such customer experience remain largely unexamined. We explore this dimension of volume-based learning in a setting where doctors at an outsourcing firm complete radiological reads for hospital customers. We examine more than 2.7 million cases read by 97 radiologists for 1,431 customers and find evidence supporting the benefits of customer-specific experience accumulated by individual radiologists. Additionally, we find that variety in an individual’s customer experience may increase the rate of individual learning from customer-specific experience for a focal task. Finally, we find that the level of experience with a customer for the entire outsourcing firm also yields learning and that the degree of customer depth moderates the impact of customer-specific experience at the individual level. We discuss the implications of our results for the study of learning as well as for providers and consumers of outsourced services.

*Key words:* customer specificity; experience; healthcare; learning; outsourcing

*History:* Published online in *Articles in Advance* December 20, 2012.

## 1. Introduction

*The division of labour, by reducing every man’s business to some one simple operation, and by making this operation the sole employment of his life, necessarily increases very much the dexterity of the workman. —Adam Smith*

As noted by Adam Smith (1776/1904, §I.1.6), the division of labor has served as a central driver of economic progress. Through increased specialization, individuals and organizations gain knowledge, enabling performance improvement and innovation (Skinner 1974, Newell and Rosenbloom 1981, Argote 1999). The trend toward specialization has been bolstered by institutional and technological change. With respect to the former, the opening of previously closed economies such as Brazil, China, and India have flooded the global labor markets with low-cost talent (e.g., Arora et al. 2001). In terms of the latter, innovations in information and communication technologies have created the opportunity to divide work into smaller pieces and send it around the world to be completed (Zuboff 1988, Autor et al. 2002).

This increasing atomization of work has also reshaped the boundaries of the firm (Levy and Murnane 2004, Levy 2008, Malone et al. 2011). In a wide variety of settings, from manufacturing to call centers and software services to healthcare services, a number of tasks that were once done within a focal firm are now contracted out to external service providers. Work may be outsourced for many reasons, but one of the key rationales is to take advantage of the expertise that outsourcers build through volume-based learning (Huckman et al. 2009, Narayanan et al. 2009). This idea draws on the concept of the learning curve (Yelle 1979, Argote 1999, Lapré and Nembhard 2010), as outsourcers can combine volume from multiple customers to build experience and thus improve their productivity.

Not only is outsourcing increasing—in part due to the opportunities for volume-based learning—but outsourcing is also changing the industrial landscape in ways that affect how we conceptualize the study of learning. Prior studies of organizational learning highlight that the

knowledge gained can vary dramatically from one unit of output to the next based on the characteristics of the work being done (Mishina 1999, Lapré et al. 2000, Argote and Miron-Spektor 2011). This tradition of work has highlighted the important, but largely distinct, roles of intraorganizational learning (e.g., Argote and Ophir 2002) and interorganizational learning (e.g., Ingram 2002). Whereas intraorganizational learning has focused on “internal” dimensions that are independent of things outside the firm (e.g., the number of units the organization produced, how teams are organized), interorganizational learning has centered on “external” dimensions (e.g., competitors’ experience).

Outsourcing provides a context in which internal and external distinctions are increasingly blurred. For example, as noted previously, outsourcing offers the promise of combining experience from multiple customers to increase aggregate volume. Therefore, a key dimension upon which a unit of output can vary is the end customer to whom it is delivered. However, *customer experience*—the experience gained with a focal customer—is both an internal dimension (e.g., individual or firm experience gained) and an external dimension (e.g., exposure to a variety of customers).<sup>1</sup> Though the increased use of outsourcing has led to a rise in the number of customer–supplier interactions, the learning benefits of customer experience remain largely unexamined. An important exception is Ethiraj et al. (2005), who theorize about, but find limited evidence of, learning from customer experience in outsourced software projects.

Why might customer experience be an important determinant of learning in service contexts? Because of the interdependent nature of services, the customer and outsourced provider must interact to “coproduce” service output (Larsson and Bowen 1989). By repeatedly interacting with the same customer, an individual may learn the customer’s standard operating procedures (March and Simon 1993, Boone et al. 2008), improve her communication and coordination with the customer (Arrow 1974, Weber and Camerer 2003, Ko et al. 2005), and learn or transfer new knowledge from the customer (Simonin 1997, Inkpen and Tsang 2007). Therefore, our first area of exploration examines customer learning at the level of individual workers.

In addition to examining the overall effect of individual customer learning, we also consider a key factor that may affect the rate at which individuals learn from focal customer experience—an individual’s variety of experience across customers. Drawing on recent work examining learning from varied experience (i.e., related to, but different from, the focal task; see Schilling et al. 2003, Narayanan et al. 2009, Staats and Gino 2012), we consider how experience with other customers may affect an individual’s rate of learning with respect to a focal customer. In particular, although prior work does not

examine customer experience, its underlying theory suggests that varied experience may have a complementary effect whereby individuals use knowledge gained across areas (in this case, customers) to learn at a faster rate (Hargadon and Sutton 1997, Haunschild and Sullivan 2002, Clark and Huckman 2012). Thus, we ask whether greater variety in the customers with whom an individual works increases her rate of learning from customer-specific experience.

In addition to examining customer learning at the individual level, we must also account for the fact that learning can occur at the level of either the individual or the organization (Walsh and Ungson 1991, Kim 1993, Argote and Ingram 2000, Reagans et al. 2005). Therefore, we add to our analysis an examination of the effect of organizational customer experience. Finally, although individual and organizational customer experience may each have independent effects on individual performance, it is not clear whether and how they interact to affect performance. This question is important because prior theory suggests that the two types of experience could have a complementary or a substitutive effect on individual performance—in other words, the total effect from individual and organizational customer experience could be greater (a complementary effect) or lesser (a substitutive effect) than the sum of its individual effects. A complementary effect is possible as individual customer experience could build absorptive capacity (Cohen and Levinthal 1990, Lubatkin et al. 2001, Inkpen and Tsang 2007) that helps an individual make better use of the organization’s knowledge. Further, greater organizational knowledge may increase the learning an individual gleans from each unit of customer experience as she becomes better able to connect different pieces of information to gain a causal understanding of a situation (Bohn 2005, Bohn and Lapré 2011). Alternatively, the effect may be substitutive to the extent that individual and organizational experience both capture the same underlying knowledge about a customer (Walsh and Ungson 1991, Argote and Ingram 2000), or an individual with more experience becomes more likely to ignore or not use the knowledge of others (Weiss et al. 1999, Schwab 2007). Therefore, our final area of exploration considers whether and how customer experience at the *individual* level interacts with that at the *organizational* level to affect individual performance. That is, are these two types of customer experience complements or substitutes?

One of the likely reasons that customer experience has received little attention in the academic literature is that finding an appropriate research setting is quite difficult. An ideal setting includes not only individuals working for many customers, outcome measures that can be tied clearly to individuals, and a panel of sufficient length to exhibit learning, but it also includes an unbiased data-generation process for matching employees with customers (e.g., a process that does not assign better or

faster workers to repeat customers). The setting for this paper, outsourced teleradiology, permits us to address each of these issues. Our data include information from July 2005 through December 2007 on 2,766,209 cases for 1,431 customers read by 97 radiologists working at OutsourceCo (a pseudonym), one of the largest teleradiology firms in the United States. Further, as we detail later, OutsourceCo's computer-based algorithm for assigning work reduces concerns about nonrandom assignment, biasing our empirical estimates.

In §2, we motivate our hypotheses. We then describe the details of our empirical setting (§3), introduce our data (§4), and discuss our empirical results (§5). Finally, we offer concluding remarks in §6.

## 2. Customer Experience and Learning

That greater cumulative experience leads to improved performance—the learning curve—is one of the more robust phenomena in the study of organizations (Yelle 1979, Argote 1999, Lapré 2011). This relationship has been identified at several levels of analysis—individuals, teams, and firms (e.g., Newell and Rosenbloom 1981, Argote et al. 1990, Pisano et al. 2001). Despite the importance of the volume of cumulative experience, recent work suggests that the specific traits of individual units of experience need to be considered in determining their contribution to learning (Mishina 1999, Lapré et al. 2000, Argote and Miron-Spektor 2011). Below, we explore why one of these traits—the customer to whom a service is provided—may prove important in determining learning and performance in a focal task.

### 2.1. Customer Experience for Individual Providers

In settings such as outsourced services, where tasks are completed for many different customers, working with a specific customer may lead to better performance as a result of improved coordination and knowledge transfer. With respect to coordination, because of the interdependent nature of services, the customer and outsourced provider must interact to “coproduce” many services (Larsson and Bowen 1989). For example, in outsourced radiology, a technician at a hospital takes the image and a doctor at the hospital requests that the outsourced radiologist read the image (and may provide specific, written instructions with the read request); the actions of both of these individuals at the customer organization affect the outsourced radiologist's ability to complete her work.

Generalizing this example from our setting, one finds several reasons why repeated interaction with a given customer may improve an individual's ability to provide outsourced services to that customer. First, repeated experience with a customer may provide an outsourcer with insight into that customer's standard operating procedures and may allow more efficient execution of work (March and Simon 1993, Boone et al. 2008). Second, different organizations often use varying language to describe similar phenomena (Arrow 1974, Weber and

Camerer 2003, Ko et al. 2005). As an individual provider gains experience with a specific customer, she may be better able to communicate with employees at that customer (in addition to any specific individuals with whom she may work repeatedly), aiding in the transfer of knowledge (Szulanski 1996, 2000). In our empirical setting such improved communication is likely to manifest itself in written messages, rather than verbal ones. Prior work highlights the challenge in successfully coding and decoding written messages (Arrow 1974). Third, given that customers are often reticent to share information with an outsourced provider (Metiu 2006), repeated interaction may increase trust and build relationship-specific capital (Uzzi 1997, Lubatkin et al. 2001, McEvily et al. 2003). Again, this effect could occur between an individual at the outsourced provider and an individual at the customer as they work together, or more generally when an individual at the outsourced provider works with multiple people at a customer. For example, with repeated experience a referring physician may be more likely to include additional information in the request that is sent to the radiologist (such as guidance on the specific anatomy to examine). These latter two points—communication and information sharing—are particularly salient in outsourced radiology where the coordination between parties may not be sequential, but rather reciprocal (i.e., requiring ongoing, mutual adjustments; see Thompson 1967, Argote 1982), across multiple reads.

Although theory suggests that prior experience with a customer may improve coordination and knowledge transfer, it is not clear if this theory will translate to the teleradiology context we study, and to outsourcing more generally. A common claim is that activities that are ideal candidates for outsourcing are “commoditized,” thus suggesting that aspects such as customer characteristics, should *not* impact the relationship between experience and performance. Commoditized activities tend to be well specified, or codified, which allows clear contracts to be written between outsourcers and customers and allows process and product specifications to be transferred easily between those parties. For example, clear standards can be set for the formulation of chemical compounds or the assembly of cellular phones, both of which are activities that are often outsourced.

In contrast to this view, Steinbrook (2007, p. 7) suggests that experience with a customer may play a significant role in determining teleradiology performance, noting,

Physicians may be less likely to know the radiologists who read their patients' studies, and there may be more opportunities for miscommunication and misunderstandings. A teleradiologist will often have no information about the patient beyond that contained in the study requisition.

Wachter (2006, p. 662) in quoting the chief executive officer of one of the largest teleradiology firms, echoes

this perspective in describing how even in teleradiology, compared with on-site interpretation, the radiologist and doctor interaction is maintained: “You can’t reach over and slap [the radiologist] on the back, but every other aspect of the interaction is preserved.”

The claim that radiological interpretation benefits from familiarity with referring physicians (i.e., customers) suggests that there may be significant benefits derived from customer experience in a teleradiology setting. To fully examine the customer specificity of individual experience, however, it is necessary to consider an additional dimension of experience. Namely, just as it is possible to gain customer experience, it is also possible to gain experience specific to a given knowledge domain. Prior work studying software development finds evidence for such domain specificity (Boh et al. 2007, Kang and Hahn 2009). In some cases, the choice of domain may limit activity to a specialized population of workers. For instance, an individual suffering from brain cancer is likely to visit a neurologist or neurosurgeon, whereas an individual suffering from prostate cancer will visit a urologist. In many other contexts, however, the same worker may complete the activity regardless of the domain examined. For example, in this study, a unit of output is a radiological read, which many radiologists can perform regardless of whether the study was conducted on different body parts such as the head, pelvis, or abdomen.

Customer–domain experience may have a greater effect on individual performance than does customer experience in other domains (though we expect both to have a greater effect on performance than the final category of experience with other customers). Different domains have domain-specific terminology and practices. These practices may vary across hospitals making the customer–domain experience most relevant for performance for a focal task. Further, given the need for domain specialization, most hospitals are divided according to domain. For example, the department of cardiology has primary responsibility for heart conditions, and the department of orthopedics is tasked with musculoskeletal issues. Therefore, when executing tasks for a given customer–domain combination, an individual radiologist in our sample is likely to work with the same subgroup of referring physicians within a hospital and build the important ties mentioned above. Given all of these factors, we offer the following related hypotheses.

**HYPOTHESIS 1A (H1A).** *An individual’s customer–domain experience has a more positive effect on performance of a focal task than experience gained from the same customer in different domains.*

**HYPOTHESIS 1B (H1B).** *An individual’s customer–domain experience has a more positive effect on performance of a focal task than experience gained from all other customers.<sup>2</sup>*

## 2.2. Variety in Individual Customer Experience

Hypothesis 1 details why we expect customer-specific experience to have a greater effect on individual performance than all other types of experience. In addition to understanding the main effect of customer experience on individual performance, related work on specialization and variety in task experience (Boh et al. 2007, Narayanan et al. 2009) suggests that it is important to examine also the interaction effects of different types of experience (Clark and Huckman 2012, Staats and Gino 2012). In other words, although specialized experience (in our case, customer experience) may have a greater direct effect than varied experience on the individual performance of a focal task, varied experience may prove useful in increasing the learning derived from specialized experience (Lapr e and Nembhard 2010).

There are several reasons why varied experience (in this case, the distribution of experience across other customers) may increase an individual’s rate of learning from customer experience in the focal task. When working for different customers, an individual may identify best practices from one customer that can be transferred to another (Hargadon and Sutton 1997, Bohn 2005, Huckman and Staats 2011) or may recognize higher-order principles that affect multiple customers (Schilling et al. 2003, KC and Staats 2012). Literature on varied experience also suggests that by working across multiple areas, an individual may change her learning process by reconsidering underlying assumptions, processing data in new ways, and searching for deeper, more causal explanations—all of which may lead to learning at a faster rate (Piaget 1963, Ellis 1965, Haunschild and Sullivan 2002).

Alternatively, individual variety in experience may slow individual learning within a focal customer. For example, a greater variety in experience could prove cognitively distracting (Monsell 2003), making it harder for an individual to learn from her present experience. However, prior work suggests that over time, the distraction effects of variety are likely outweighed by its benefits (Staats and Gino 2012). We therefore hypothesize the following.

**HYPOTHESIS 2 (H2).** *Individual variety in customer experience will have a positive, moderating effect on the relationship between individual customer experience and the performance of a focal task.*

## 2.3. Customer Experience Throughout the Organization

Although individuals complete tasks in an organization, individuals may also learn from the experience that the organization accrues (Argote 1999, Reagans et al. 2005, Lapr e and Nembhard 2010). Organizational experience can improve individual performance in multiple ways. With repeated experience, an organization may develop operating procedures and routines for completing work

(Nelson and Winter 1982). These routines may be captured explicitly in standardized work practices (Staats et al. 2011) or enterprise information technology systems (Brunner 2009), or alternatively, they may be captured tacitly in the norms and culture of an organization (Nonaka 1994, Nonaka and Takeuchi 1995). Over time, the organization may build a *capability*, defined as the consistent ability to do that which is intended, out of these routines (Dosi et al. 2000, Hayes et al. 2005).

Organizational experience may also improve individual performance through better problem solving. Depending on the setting, an individual may learn by watching others complete the same task (Bandura 1977, Gino et al. 2010, KC and Staats 2012). Additionally, organizational experience creates a reservoir of knowledge (Walsh and Ungson 1991, Argote and Ingram 2000), and individual members may be able to draw on that knowledge by seeking the help of others when they encounter difficulties (Lee 1997, Hofmann et al. 2009).

In this study we focus on organizational experience gained with a specific customer. There are several reasons why this type of experience may aid individual performance. The organization may use the knowledge gained from its experience to develop focused practices to serve a customer. For example, in one context, Indian software services, outsourcers often set up off-shore delivery centers (ODCs) to execute work for customers (Arora et al. 2001). One objective of an ODC is to capture customer learning across projects. Also, in contexts where customers are involved in the production of a service (Larsson and Bowen 1989)—for example, healthcare or software—the customer may also learn from its experience with the outsourcer, changing its own practices to work more effectively. This mutual adaptation may lead to organizational-level learning from customer experience. Overall, we hypothesize the following.

**HYPOTHESIS 3 (H3).** *An organization's customer experience has a positive effect on individual performance of a focal task.*

#### **2.4. Individual and Organizational Customer Experience: Complements or Substitutes?**

As outlined in Hypotheses 1A, 1B, and 3, both individual customer experience and organizational customer experience are likely to have independent beneficial effects on individual learning and performance. An important and unexamined question is how these two types of experience interact with one another to affect individual performance. The answer to this question has meaningful theoretical consequences, in part because theory suggests that individual- and organizational-level customer experience could be either complements or substitutes.

The argument in favor of complements rests on the theoretical idea of absorptive capacity—it often takes

one's own knowledge to utilize fully the knowledge held by others (Cohen and Levinthal 1990). This is because an individual's existing knowledge not only helps her to identify, acquire, and understand external knowledge but also allows her to transform and exploit that knowledge (Mowery and Oxley 1995, Zahra and George 2002). Through identifying, acquiring, and understanding external knowledge, an individual is likely to see a direct effect of organizational experience on individual performance (see Hypothesis 3).

It is in the transformation and exploitation of external knowledge that the potential complementarity between individual and organizational customer experience arises. The literature on alliances finds that absorptive capacity may not be just a general characteristic but also a dyadic one between two partners (Lane and Lubatkin 1998, Mowery et al. 2002). Similarly, if an individual's customer experience builds absorptive capacity in understanding a customer, that individual may be better positioned to transform and use the knowledge arising from her organization's experience with that same customer (Lubatkin et al. 2001). When an individual completes a task for a customer, she has an opportunity to learn about that customer. However, learning requires making connections between different pieces of information to gain a causal understanding of a situation (Bohn 2005, Bohn and Lapré 2011). When completing a task, an individual typically does not have complete knowledge and understanding of the situation. Therefore, organizational experience with a customer might help fill in missing information. Further, learning and innovative solutions often arise from combining existing knowledge in new ways (Fleming and Sorenson 2004). Together, these conditions suggest that individual and organizational experience with a particular customer can be mutually reinforcing.

Alternatively, individual- and organizational-level customer experience may act as substitutes. In other words, the joint benefit of individual and organizational experience may be less than the sum of the two individual effects (Schwab 2007). First, it is possible that the knowledge gained from either individual or organizational experience may capture the same underlying information. If information is at least partially redundant, then either type of experience, by itself, could be sufficient to improve performance (Walsh and Ungson 1991, Argote and Ingram 2000). Second, if adaptation by the customer is the key driver of learning and improved performance (Lubatkin et al. 2001, Inkpen and Tsang 2007), then either individual or organizational customer experience could trigger such change, causing individual and organizational experience to have similar effects on learning. Finally, the salience or increased understanding from individual knowledge may affect an individual's use of knowledge held at the organizational level (Levinthal and March 1993). Namely, prior research

shows that as an individual has increased experience, she may be more likely to ignore the knowledge of others (Weiss et al. 1999, Schwab 2007). Together, these factors suggest that individual and organizational customer experience may have a substitutive effect on individual performance.

Given the compelling motivation for either a complementary or a substitutive interaction, we specify competing hypotheses as follows.

**HYPOTHESIS 4A (H4A).** *Organizational customer experience will have a positive, moderating effect (complementary interaction) on the relationship between individual customer experience and the performance of a focal task.*

**HYPOTHESIS 4B (H4B).** *Organizational customer experience will have a negative, moderating effect (substitutive interaction) on the relationship between individual customer experience and the performance of a focal task.*

### 3. Setting—Outsourced Teleradiology Services

Radiology is a medical specialty that involves performing and interpreting imaging studies (e.g., x-ray, computed tomography (CT), magnetic resonance imaging (MRI), ultrasound, nuclear medicine) to diagnose and treat disease. Historically, both the performance and interpretation of radiological studies occurred within the boundaries of a single provider organization, such as a hospital or radiology group practice. During the past decade, however, provider organizations have experienced a dramatic increase in the volume of radiological studies they perform and, therefore, need to interpret. Between 1999 and 2004, cumulative growth in the volume of all physician services per Medicare<sup>3</sup> beneficiary was 31%; analogous figures for radiological services, however, were much larger, at 62% across all radiological services, 112% for nuclear medicine, and 140% for nonbrain MRI (Steinbrook 2007). This growth is potentially due to several factors, the most prominent being technological advancements in imaging (Levy and Goelman 2005, Steinbrook 2007) and the practice of “defensive medicine” to avoid the threat of malpractice liability (Studdert et al. 2005).

The rapid growth in imaging studies has outpaced growth in the supply of radiologists to read them. In addition, hospitals, particularly smaller community facilities, are not able to find or afford employed radiologists to provide “off-hours” coverage for the interpretation of the growing number of studies performed on an emergency basis. This dual need for additional capacity and 24-hour coverage has fueled demand for teleradiology—the computerized transmission and interpretation of radiological studies outside the physical locations in which those studies are conducted.

Teleradiology services can be provided by a hospital or a practice’s employed radiologists (e.g., from their homes outside of traditional business hours) or by an outsourcer either in the United States or abroad.<sup>4</sup> Surveys of over 1,900 radiologist practices indicate that between 2003 and 2007, the percentage of practices outsourcing some portion of their radiology services nearly tripled from 15% to 44% (Lewis et al. 2009). It is reasonable to expect that this percentage has grown in recent years as a result of continued increases in volume and technological advances in imaging.

The data for our study were obtained from OutsourceCo, one of the largest U.S.-based providers of outsourced teleradiology services. OutsourceCo employs radiologists who are board certified and licensed to practice radiology in the United States. Approximately 55% of its radiologists are based in the United States, working from either their homes or one of several reading centers owned by OutsourceCo. The remainder is based overseas, again working either from home or a reading center. OutsourceCo has more than 1,400 client sites—mostly hospitals and group radiology practices—across the United States.

Most of the studies interpreted by outsourced teleradiology providers can be categorized based on the technology used to generate them. The most common technologies used in these studies are the following.

- *X-ray*: The oldest radiologic technology, x-ray involves the use of ionizing electromagnetic radiation to view various parts of the human anatomy. It accounts for 4% of OutsourceCo’s case volume.

- *CT*: Introduced in the 1970s, CT allows for the generation of three-dimensional images of various anatomical regions by combining a series of two-dimensional images taken around an axis of rotation. It accounts for 84% of OutsourceCo’s case volume.

- *MRI*: In contrast to x-ray and CT, MRI relies on a magnetic field rather than ionizing radiation to generate images of various anatomical regions. In addition to reducing exposure to radiation, MRI also provides greater contrast between various soft tissues in the body than can be obtained with either x-ray or CT. It accounts for 1% of OutsourceCo’s case volume.

- *Ultrasound*: Ultrasound involves the use of high-frequency acoustics to obtain real-time images of various parts of the body. It does not involve the use of ionizing radiation and tends to be cheaper and more portable than both CT and MRI. One of the most common uses of ultrasound is for routine obstetric diagnosis and monitoring. It accounts for 10% of OutsourceCo’s case volume.

- *Nuclear medicine*: Nuclear medicine involves combining radioactive isotopes with other pharmaceutical compounds to examine cellular function and physiology. It accounts for 1% of OutsourceCo’s case volume.

Customers upload studies performed at their hospitals or offices to OutsourceCo’s proprietary system. Each study is initially processed by an administrative assistant,

who assigns it to the queue of an *eligible* radiologist who is on duty at that time. For any given study, an eligible radiologist is one who is trained in the relevant anatomical area (e.g., head, spine, abdomen) and technology (e.g., CT, MRI, nuclear medicine). In addition, an eligible radiologist must be licensed to practice medicine in the state—and be a member of the medical staff of the hospital—where the image was generated. Given these requirements, the typical radiologist at OutsourceCo is eligible to practice in over 35 states and at more than 400 hospitals. During our study period, more than 90% of OutsourceCo’s radiologists performed reads using each of the technologies described above. In terms of anatomical specialties, all but one of OutsourceCo’s radiologists performed reads in at least 7 of the 11 possible anatomical areas, and 94% performed reads in at least 10 such areas.<sup>5</sup>

Conditional on a radiologist being on duty and appropriately trained and licensed, the assignment of cases to radiologists is random. A radiologist completing tasks more quickly will have the opportunity to complete more tasks, but the OutsourceCo system does not assign “more important” tasks to specific doctors. Once a case has been read, the radiologist completes a report that is checked for clerical and administrative completeness by the assistant before being forwarded to the customer.

## 4. Data and Empirical Strategy

### 4.1. Data

Images arriving at OutsourceCo’s central image distribution system are assigned primarily on a reading radiologist’s current workload relative to her capacity. We note that, within the universe of customers, domains, and technologies for which a radiologist is eligible to provide services, the customer, domain, and technology characteristics of an image are not factored into the assignment algorithm. Our data include information on every radiological image assigned to OutsourceCo radiologists between July 2005 and December 2007. Data include unique identifiers for each radiologist and each ordering customer, the body part imaged (i.e., domain), the technology used to take the image, and time stamps for when a case was received and when the radiologist finished reading it. The raw data contain an observation for each image, though a single case (i.e., one patient) may consist of multiple images. Time stamps are case specific and not image specific. Accordingly, we are only able to calculate estimated read times at the case level. To do so, we collapse the image-level observations to case-level observations, retaining indicators for body location, technology, and the number of images in addition to unique identifiers for the reading radiologist and customer. The resulting data set includes 2,766,209 cases read by 97 radiologists for 1,431 customers over the 30-month period covered by the data.

### 4.2. Dependent Variable

Our outcome of interest is the length of time it takes a radiologist to read a case (*READTIME*). Time to completion is not only a commonly used performance measure in the learning literature (Pisano et al. 2001, Reagans et al. 2005), but it is also an important measure for operational performance in this context for both OutsourceCo (which garners greater productivity from its radiologist labor) and its customers (who receive a more timely response for what are often emergency cases). In theory, an additional performance variable is performance quality; however, only 0.3% of our cases are characterized by a “discrepancy.” Given this low rate and the fact that many of these discrepancies result from a need for clarification rather than deficient performance, we are not able to examine quality performance in this study.

To calculate *READTIME*, we rely on information about when each case is received (time in) and when the radiologist completes the read (time out). Time in, however, does not necessarily represent when the radiologist begins reading a case. For example, when a case is assigned to a reading radiologist, it enters his queue. The radiologist may read his queue in the order received or may choose to rearrange images to better suit his workflow. Therefore, we make two key assumptions, derived from our discussions with personnel at OutsourceCo, to calculate *READTIME*. First, we assume that during a radiologist’s work shift, time out for the prior case is a reasonable approximation for the start time of the current case. Radiologists work on cases sequentially and do not start a new case until they have finished the prior case. Second, we assume that any elapsed time between the time out of the current case and the time out of the prior case greater than 30 minutes represents a “break” between a radiologist’s shifts. The 30-minute break window was determined based on the data. Specifically, we examined the average and standard deviation of the difference between the time out of a radiologist’s current read and the time out of the prior read. The 30-minute cutoff is approximately equivalent to the average plus four standard deviations. Nevertheless, we examine the robustness of our results using shorter and longer break windows.

Using these assumptions, we partition each radiologist’s list of cases into shifts using the break window described above. For each radiologist and each shift, cases are ordered by time out, and *READTIME* is calculated as follows.

1. First case of a shift, where read time equals time out minus time in and
2. All subsequent shift cases, where read time equals time out for the current case minus time out for the prior case.

### 4.3. Independent Variables

To examine our hypotheses, we split the prior experience of individual radiologists into segments that enable

us to estimate the learning benefit of customer–domain experience relative to all other types of experience. As a baseline model, we divide a radiologist’s prior experience into two categories. The first, *IndvlCustomer*, represents what we term *individual customer experience*, the cumulative number of prior cases read by a radiologist for the customer of the current case. The second, *IndvlOtherCustomer*, represents the cumulative number of prior cases read by a radiologist for all customers other than the customer of the current case. We next divided experience within each of the two customer categories by domain to create four categories of experience. These measures consist of components that are unique to the customer and the domain, the customer but not the domain, the domain but not the customer, or neither category. Domains are defined based on the body part imaged and are categorized consistent with the subspecialties recognized by the American College of Radiology and the Radiological Society of North America and with the way radiology departments are organized in typical academic medical centers in the United States. These categories include abdomen, body (combination images), brain, breast, cardiovascular, chest, gastrointestinal/genitourinary, head and neck, musculoskeletal, obstetrical, and spine (see Table 1).

Based on these categories, *IndvlCustomerDomain* represents the cumulative number of prior cases read by a radiologist in the domain, and for the customer, of the current case; *IndvlCustomerOtherDomain* represents the cumulative number of prior cases (outside the domain of the current case) read by a radiologist for the customer, of the current case; *IndvlOtherCustomerDomain* represents the total cumulative number of prior cases for a given radiologist that match the domain (e.g., body, chest, spine), but not the customer, of the current case; and *IndvlOtherCustomerOtherDomain* represents the cumulative number of prior cases read by a given radiologist in all domains and for all customers other than those of the current case. Figure 1 provides an illustration of how these measures relate to one another. Having constructed these four, collectively exhaustive combinations of customer and domain experience, we use them to test Hypotheses 1A and 1B.

To test Hypothesis 2, we examine the extent to which the experience of a reading radiologist is distributed across a variety of customers. Specifically, we measure the degree to which a radiologist’s cumulative volume prior to the current case is concentrated by customer. To do so, we use a Herfindahl-style index of customer concentration. Thus *IndvlCustomerFocus* is produced by first measuring, for each case, the share of that radiologist’s prior volume devoted to each customer. These volume shares are then squared and summed, producing a measure for which higher values indicate a greater degree of customer concentration (i.e., less variety). The interaction of this measure with *IndvlCustomerDomain* allows a test of Hypothesis 2.

**Table 1** Distribution of Images by Domain and Technology

Variable	Frequency (%)
<b>Domains</b>	
<i>Abdomen</i>	5.5
<i>Body</i>	37.8
<i>Brain</i>	32.3
<i>Breast</i>	0.0
<i>Cardiovascular</i>	0.2
<i>Chest</i>	12.6
<i>GI/GU</i>	1.7
<i>Head and neck</i>	2.4
<i>Musculoskeletal</i>	1.3
<i>Obstetrics</i>	2.5
<i>Spine</i>	0.0
<i>Other</i>	3.6
<b>Technologies</b>	
<i>CT</i>	84.5
<i>MRI</i>	0.9
<i>NM</i>	1.0
<i>US</i>	10.0
<i>XR</i>	3.6

Note. GI/GU, gastrointestinal/genitourinary; NM, nuclear medicine; US, ultrasound; XR, x-ray.

To test Hypothesis 3, we create a variable, *OrgCustomer*, which captures the depth of OutsourceCo’s experience with a particular customer. Specifically, *OrgCustomer* is the total number of prior cases a customer has sent to OutsourceCo. To distinguish this variable from the customer experience of the current reading radiologist (and to facilitate the interactions necessary to test Hypothesis 4), we subtract the current reading radiologist’s experience with the current customer. Thus, *OrgCustomer* is the cumulative number of prior cases the current customer has sent to OutsourceCo less

**Figure 1** Segmenting Individual Experience by Customer and Domain Relative to the Current Case

the current radiologist’s cumulative experience (across all domains) with that customer. In our models, we examine this variable in both linear and discrete forms. The discrete form consists of three categories representing the linear variable split into thirds: *OrgCustomer1*, *OrgCustomer2*, and *OrgCustomer3*. This categorical version is intended to facilitate the interpretation of the interactions with radiologist experience and to reduce the correlation present between *OrgCustomer* and *IndvlCustomerDomain* (correlation = 0.64). Specifically, the correlation between *IndvlCustomerDomain* and *OrgCustomer2* and *OrgCustomer3* is 0.26 and 0.46, respectively. These notably lower levels of correlation increase our confidence that the thirds of *OrgCustomer* and the continuous *IndvlCustomerDomain* are in fact capturing different characteristics when we interact them to test Hypothesis 4. Table 2 contains summary statistics and correlations for our key variables of interest.

#### 4.4. Empirical Models

To examine the impact of various types of experience on individual performance, we use ordinary least squares regression to estimate a series of exponential learning curve models. We rely on the exponential form of the learning curve to examine our hypotheses because as Lapré and Tsiriktsis (2006, p. 356) have demonstrated, “For the exponential form, accounting for prior experience is a nonissue—omission of prior experience will not bias learning-rate estimates.” Given that our data only include the experience of radiologists with *OutsourceCo* between July 2005 and December 2007—and no experience accumulated prior to that window—the exponential form avoids the bias problem that would arise with the power form.

**4.4.1. Individual Customer Experience.** To test for customer specificity at the individual level (Hypotheses 1A and 1B), we estimate the following:

$$\begin{aligned} \ln(\text{READTIME}_{hijt}) &= \alpha_t + \gamma_{hi} + \beta_1 \text{IndvlCustomerOtherDomain}_{hij} \\ &+ \beta_2 \text{IndvlCustomerDomain}_{hij} \\ &+ \beta_3 \text{IndvlOtherCustomerDomain}_{ij} \\ &+ \beta_4 \text{IndvlOtherCustomerOtherDomain}_{ij} \end{aligned}$$

$$\begin{aligned} &+ \beta_5 \text{IndvlCustomerFocus}_{ij} \\ &+ \beta_6 \text{Backlog}_{ij} + \varphi_1 X_j + \varepsilon_{hijt}, \end{aligned} \quad (1)$$

where  $\gamma_{hi}$  and  $\alpha_t$  are fixed effects for customer  $h$ –radiologist  $i$  pairings and year  $t$ , respectively. The former captures time-invariant characteristics of customer–radiologist pairs that may influence  $\text{READTIME}_{hijt}$ ; the latter captures changes in the average value of  $\text{READTIME}_{hijt}$  for the sample over time.  $\text{Backlog}_{ij}$  represents the number of cases in the queue of radiologist  $i$  when reading case  $j$ ;  $X_j$  represents a vector of characteristics for individual case  $j$ , including binary indicators for the technology employed and the knowledge domain addressed to control for differences in the average read time across these dimensions. The model also includes the number of images for case  $j$  to capture the amount of information a reading radiologist must consider to complete the current case.  $\text{IndvlCustomerOtherDomain}_{hij}$ ,  $\text{IndvlCustomerDomain}_{hij}$ ,  $\text{IndvlOtherCustomerDomain}_{ij}$ ,  $\text{IndvlOtherCustomerOtherDomain}_{ij}$ , and  $\text{IndvlCustomerFocus}_{ij}$  are as described previously, with  $\text{IndvlCustomerDomain}_{hij}$  the key variable of interest. Given that negative values of  $\beta_1$ ,  $\beta_2$ ,  $\beta_3$ , and  $\beta_4$  are associated with better performance (i.e., shorter read times), Hypothesis 1A predicts that  $\beta_2$  will be less than  $\beta_1$ , and Hypothesis 1B predicts that  $\beta_2$  will be less than  $\beta_3$  and  $\beta_4$ .

**4.4.2. Organizational Customer Experience.** To test Hypothesis 3 related to the benefits of an organization’s depth of experience with a particular customer, we examine the following models:

$$\begin{aligned} \ln(\text{READTIME}_{hijt}) &= \alpha_t + \gamma_{hi} + \delta_1 \text{OrgCustomer}_{hj} \\ &+ \varphi_1 X_j + \varepsilon_{hijt}, \end{aligned} \quad (2)$$

$$\begin{aligned} \ln(\text{READTIME}_{hijt}) &= \alpha_t + \gamma_{hi} + \delta_2 \text{OrgCustomer2}_{hj} \\ &+ \delta_3 \text{OrgCustomer3}_{hj} + \varphi_1 X_j + \varepsilon_{hijt}, \end{aligned} \quad (3)$$

where  $\gamma_{hi}$ ,  $\alpha_t$ , and  $X_j$  are as previously described. In (2), *OrgCustomer* enters in linear form; in (3), it enters in discrete thirds (with *OrgCustomer1* omitted).

**4.4.3. Customer Experience Interactions.** To examine Hypotheses 2 and 4, we interact each segment of the radiologist’s prior customer experience with either an

**Table 2 Summary Statistics for Key Variables**

Variable	Mean	Std. dev.	(1)	(2)	(3)	(4)	(5)	(6)	(7)
(1) <i>READTIME</i>	4.99	8.90							
(2) <i>IndvlCustomerDomain</i>	43.51	71.75	−0.058						
(3) <i>IndvlCustomerOtherDomain</i>	106.42	155.21	−0.076	0.650					
(4) <i>IndvlOtherCustomerDomain</i>	7,579.36	8,034.62	−0.112	0.486	0.228				
(5) <i>IndvlOtherCustomerOtherDomain</i>	20,295.17	17,646.61	−0.147	0.262	0.453	0.569			
(6) <i>IndvlCustomerFocus</i>	0.009	0.012	0.106	−0.086	−0.096	−0.221	−0.270		
(7) <i>OrgCustomer</i>	829.61	1,075.47	−0.013	0.638	0.340	0.367	0.111	−0.115	
(8) <i>Backlog</i>	4.79	3.86	−0.130	0.091	0.111	0.203	0.261	−0.109	0.037

individuals' variety of customer experience (*IndvlCustomerFocus*) or the customer's depth of interaction with *OutsourceCo* (*OrgCustomer*). This involves merging the variables from (3) with those from (1) and creating the appropriate interactions as follows:

$$\begin{aligned}
 \ln(\text{READTIME}_{hijt}) &= \alpha_t + \gamma_{hi} + \beta_1 \text{IndvlCustomerOtherDomain}_{hij} \\
 &+ \beta_2 \text{IndvlCustomerDomain}_{hij} \\
 &+ \beta_3 \text{IndvlOtherCustomerDomain}_{ij} \\
 &+ \beta_4 \text{IndvlOtherCustomerOtherDomain}_{ij} \\
 &+ \beta_5 \text{IndvlCustomerFocus}_{ij} + \delta_2 \text{OrgCustomer2}_{hj} \\
 &+ \delta_3 \text{OrgCustomer3}_{hj} \\
 &+ \vartheta_1 (\text{IndvlCustomerOtherDomain}_{hij} \\
 &\quad \times \text{IndvlCustomerFocus}_{ij}) \\
 &+ \vartheta_2 (\text{IndvlCustomerDomain}_{hij} \\
 &\quad \times \text{IndvlCustomerFocus}_{ij}) \\
 &+ \vartheta_3 (\text{OrgCustomer2}_{hj} \\
 &\quad \times \text{IndvlCustomerOtherDomain}_{hij}) \\
 &+ \vartheta_4 (\text{OrgCustomer3}_{hj} \\
 &\quad \times \text{IndvlCustomerOtherDomain}_{hij}) \\
 &+ \vartheta_5 (\text{OrgCustomer2}_{hj} \times \text{IndvlCustomerDomain}_{hij}) \\
 &+ \vartheta_6 (\text{OrgCustomer3}_{hj} \times \text{IndvlCustomerDomain}_{hij}) \\
 &+ \beta_6 \text{Backlog}_{ij} + \varphi_1 X_j + \varepsilon_{hijt}, \quad (4)
 \end{aligned}$$

where  $\gamma_{hi}$ ,  $\alpha_t$ ,  $X_j$ ,  $\text{Backlog}_{ij}$ , and each of the key independent variables are as previously described. Hypothesis 2 predicts that the interactions with focus (the opposite of variety) will have a negative effect on performance ( $\theta_2 > 0$ , given that positive estimates indicate longer completion time). Hypothesis 4A predicts that the interactions with the organization's customer experience will have a positive effect on performance ( $\theta_6 < \theta_5 < 0$ ), whereas Hypothesis 4B predicts that these interactions will have a negative effect on performance ( $\theta_6 > \theta_5 > 0$ ).

## 5. Results

Table 3 contains estimates from models testing our four hypotheses. We present baseline estimates related to overall customer-specific volume in column 1. The estimate on *IndvlCustomer* in column 1 is in the expected direction and larger in magnitude than the estimate on *IndvlOtherCustomer*. However, this estimate is not significant at conventional levels.

With respect to Hypotheses 1A and 1B, the estimate on *IndvlCustomerDomain* in column 2 is larger in absolute magnitude than any of the other three estimates, and

the estimate on *IndvlCustomerDomain* is significantly different from each of the other three estimates at conventional levels ( $p$ -values from  $F$ -tests are each less than 0.03). This result supports Hypotheses 1A and 1B, suggesting that individual customer–domain experience is more beneficial, on average, than other types of experience. Relative to the mean level of customer–domain experience of 43.51, an additional 1,000 cases<sup>6</sup> of experience yields a reduction in *READTIME* of approximately 13.83 seconds. This reduction in *READTIME* would result in approximately 54 additional cases read during a typical 40-hour work week, a 7.4% increase in the average weekly volume for a radiologist. This compares to a reduction of approximately 0.98 seconds from 1,000 additional units of domain experience and 0.64 seconds from the same amount of other experience. Consistent with Hypotheses 1A and 1B, these findings suggest that there is substantial customer–domain specificity in learning at the level of the individual radiologist.

We also note that the estimates on *IndvlOtherCustomerDomain* and *IndvlOtherCustomerOtherDomain* suggest that, although increases in both measures significantly improve individual performance, domain-specific experience is more beneficial than experience with other domains and other customers (column 2). An  $F$ -test of the difference between these two estimates is statistically significant ( $p < 0.001$ ). This result empirically supports why subspecialties in radiology are organized according to specific domains.

Columns 3 and 4 present models testing Hypothesis 3. Column 3 shows the results of the model in which *OrgCustomer* is entered in linear form. The estimate is negative and significant at conventional levels, suggesting that productivity improves across all radiologists the more experience *OutsourceCo* has with a particular customer. Specifically, relative to mean levels of *OrgCustomer*, a customer sending an additional 1,000 cases to *OutsourceCo* yields a reduction in *READTIME* of approximately 3.67 seconds. Similarly, the estimates in column 4 suggest that, relative to customers in *OrgCustomer1*, customers in *OrgCustomer2* and *OrgCustomer3* have values of *READTIME* that are 10.81 and 16.72 seconds faster, respectively. We note that the estimates for customers in *OrgCustomer2* and *OrgCustomer3* are significantly different from each other at conventional levels ( $p < 0.001$ ). These findings support the predictions of Hypothesis 3.

Columns 5 and 7 include estimates testing Hypothesis 2. Specifically, in these models *IndvlCustomerFocus* is interacted with our customer-specific experience variables—*IndvlCustomerDomain* and *IndvlCustomerOtherDomain*—with the *IndvlCustomerDomain* interaction constituting the key test of our hypothesis. In column 5, the *OrgCustomer* interactions are excluded. We note that the estimates on the main effect of *IndvlCustomerFocus* in columns 1, 2, 5, 6, and 7 provide

Notes. The dependent variable is  $\ln(\text{READTIME})$ . Robust standard errors in parentheses are clustered by customer–radiologist pairs. Model includes a constant term, and covariates are not reported.

\* $p < 0.1$ ; \*\* $p < 0.05$ ; \*\*\* $p < 0.01$ .

consistent and significant evidence that variety is beneficial for individual performance, as higher levels of *IndvlCustomerFocus* indicate less variety. With respect to the interaction effects, the results in column 5 suggest that variety has a complementary impact on the effect of customer-specific experience. In other words, the more variety in a radiologist's previous experience (lower levels of the focus variable), the stronger the effect of customer-specific experience on read times. However, although this estimated effect is significant with respect to the interaction with *IndvlCustomerOtherDomain*, the interaction with *IndvlCustomerDomain* is not significant at conventional levels. Thus, the results in column 5 do not provide strong support in favor of Hypothesis 2. We note, however, that in the fully specified model (4) in column 7, both interaction estimates that include *IndvlCustomerFocus* are in the expected direction and significant at conventional levels. Nevertheless, though the magnitude and significance of the interaction with *IndvlCustomerDomain* in column 7 support Hypothesis 2, the lack of a consistent finding in column 5 suggests only partial support for Hypothesis 2.

Finally, columns 6 and 7 present the results for interactions between individual and organizational customer experience. In column 6, the *IndvlCustomerFocus* interactions are excluded. We note that the estimates on the radiologist experience variables demonstrate the same pattern seen in column 2, with statistically significant differences suggesting strong evidence of radiologist domain specificity across the full sample and customer-domain specificity among customers in the first third of *OrgCustomer*. We also note that the estimates on *IndvlCustomerOtherDomain* in columns 6 and 7 are significant at conventional levels. The estimates on the main effects of *OrgCustomer2* and *OrgCustomer3* in columns 6 and 7 are similar to, though slightly lower in magnitude than, the results presented in column 4. Collectively, these findings on the main effects in columns 6 and 7 are consistent with Hypotheses 1 and 3, suggesting that customer learning takes place at the individual (among relatively new *OutsourceCo* customers) and organization levels.

The key question with respect to Hypothesis 4, however, is whether individual and organizational customer experience are complements or substitutes. The estimated interactions in columns 6 and 7 suggest a substitutive effect; note that the estimated interactions of *OrgCustomer* with *IndvlCustomerDomain* and *IndvlCustomerOtherDomain*, respectively, in both columns are positive and follow a moderating pattern. Specifically, these estimates run in the opposite direction of the main effects, suggesting that the benefit of individual customer experience is diminishing with increasing organizational customer experience. In the fully specified model in column 7, the absolute magnitude of the relevant *OrgCustomer3* interaction term equals 63% of

the *IndvlCustomerOtherDomain* main effect and 90% of the *IndvlCustomerDomain* main effect. A similar pattern, though slightly smaller in magnitude, is observed in the interaction with *OrgCustomer2*. These interaction effects for *IndvlCustomerDomain* and *IndvlCustomerOtherDomain* are significant at conventional levels and support Hypothesis 4B (over Hypothesis 4A), suggesting that individual customer specificity diminishes as *OutsourceCo* gains more experience with a particular customer.

### 5.1. Robustness

As with other studies of this nature, our results may be sensitive to the choices we have made in constructing our variables and selecting our methods. First, as described previously, measuring *READTIME* required us to define radiologist shifts by estimating breakpoints based on the elapsed time between the time out of the prior read and the time out of the current read. We use 30 minutes as the breakpoint threshold for our base models but also examine the sensitivity of our results to using 20-minute and 40-minute breakpoints; these results, reported in columns 1 and 2 of Table 4, respectively, are similar in direction, magnitude, and statistical significance to those appearing in column 7 of Table 3. Further, test statistics comparing the various estimates in each column in Table 4 for customer specificity are consistent with those reported for Table 3. Specifically, the main effect for *IndvlCustomerDomain* is greater in absolute magnitude than those for *IndvlOtherCustomerDomain* and *IndvlOtherCustomerOtherDomain*, and both of these differences are significant at the 1% level. In addition, the main effects for *OrgCustomer2* and *OrgCustomer3* are consistent in direction, magnitude, and significance with the estimates in Table 3. Finally, the results in Table 4 suggest that customer specificity is diminishing in the level of *OrgCustomer*. Collectively, the results in Table 4 suggest that our base findings are robust to changes in how breaks between shifts are defined.

Second, our base model includes *OrgCustomer* entered categorically in thirds. As noted earlier, this was done in part to reduce the correlation between *OrgCustomer* and *IndvlCustomerDomain*. A second reason for this choice relates to the interpretation of interaction effects. By dividing a linear variable into categories, or levels, the interpretation of its moderating influence on another linear variable is substantially simplified. Nevertheless, our choice to categorize *OrgCustomer* in thirds may seem arbitrary. Accordingly, we also examine our base model with *OrgCustomer* categorized in halves (above and below median) and quartiles. These results (not shown but available from the authors upon request) are consistent with the results from our base model and suggest that our findings are robust to how *OrgCustomer* is divided into discrete categories.

## 6. Discussion and Conclusion

Though many markets have traditionally been restricted by geography (Baumgardner 1988), innovations in information and communication technologies have reduced these barriers (Zuboff 1988, Autor et al. 2002). Given the ability to convert the information on a piece of paper or an image into bits (e.g., through scanning technology or digital imaging) and send those bits around the world (e.g., via the Internet), the potential market size for certain service providers is increasing, offering the opportunity for greater specialization. In turn, these effects are leading to more outsourcing (Levy and Murnane 2004, Levy 2008, Malone et al. 2011) and an increase in arm’s-length interactions between customers and suppliers. The experience that arises from these interactions, however, remains understudied.

Our results highlight the importance of learning curves in interdependent, knowledge-based work. Further, they suggest that the established relationship

between volume and performance that underpins the learning curve needs to account for the multiple dimensions of experience that can be accumulated (Lapré and Nembhard 2010, Argote and Miron-Spektor 2011). In particular, we find that both individual and organizational customer experience aid individual performance. Moreover, we find that experience across a wider variety of customers may aid the rate at which individuals learn from their own customer-specific experience. Finally, we find that individual customer specificity is moderated by the depth of the organization’s experience with a customer, suggesting that individual and organizational customer experience are substitutes.

Our findings have important theoretical and managerial implications. At the individual level, we find that both customer-specific experience and variety across customers have positive effects on individual performance, with the magnitude of the former being significantly greater than that of the latter. We also find

that variety in experience across customers can aid the rate of learning from customer-specific experience. The caveat is that increasing variety across customers leads to a simultaneous limiting of the degree to which one can gain customer-specific experience. The question thus arises as to how one should combine the seemingly contradictory approaches of increasing customer-specific experience and increasing variety across customers served. Our findings provide insight into this issue by highlighting that customer specialization and variety may be mutually reinforcing strategies (Narayanan et al. 2009, Clark and Huckman 2012, Staats and Gino 2012). The implication is that there may be limits to the benefits of both customer-specific volume and variety across customers, suggesting the need for an optimal mix of both types of experience. Future work should build on this finding through the use of field or laboratory experiments to examine the nature of this optimal mix.

Our findings in an outsourcing context offer important insights into the study of organizational and individual learning. Prior work on organizational learning highlights the important, but largely separate, roles of interorganizational (e.g., Ingram 2002) and intraorganizational learning (e.g., Argote and Ophir 2002). The shifting boundaries of firms, however, suggest the need for theory that bridges the traditional interorganizational–intraorganizational distinction. Beyond the customer specificity of individual learning, repetitive interactions with a customer may also lead to knowledge transfer across firm boundaries that could lead to changes in organizational processes. There is a need for detailed studies to understand how such learning and knowledge transfer does (or does not) occur and whether these knowledge transactions can be structured in a way that produces performance benefits comparable to (or even exceeding) what is possible within a single firm (Nickerson and Zenger 2004). Whereas studies such as Hansen's (1999) and Szulanski's (1996) examine the factors that help or hinder knowledge transfer within the firm, the shifting boundaries of firms offer the opportunity to examine *both* the cross-firm factors that lead to knowledge transfer and how those compare to and interact with within-firm factors.

Our findings also inform the strategic management literature concerning the microfoundations of organizational capability (Ethiraj et al. 2005, Felin and Foss 2005), where an important question is whether capabilities reside at the level of individuals or the organization as a whole (Staats 2012). Individuals are the actors who complete most of the work for an organization (Argote and Ingram 2000), and a large body of work highlights the key role that individual human capital plays in organizational success (Hatch and Dyer 2004, Hitt et al. 2006). Through norms, systems, and routines, however, capability may also reside at the level of the

organization. This question is not simply important in the abstract. From a strategic perspective, if customer specificity resides mainly at the level of the individual, the organization may face difficulty in leveraging its human capital to build a sustainable competitive advantage (Hatch and Dyer 2004). Instead, employees may capture rents either through salary increases or by moving to a competitor.

Our results, however, show that capability resides at both levels, as organizational and individual experience act as substitutes in their effects on performance. Thus although individuals certainly play a key role in successfully delivering a service—particularly early in a customer's relationship with the organization—customer capability may also be built at the level of the organization over time. Future work should examine the applicability of our framework in other contexts and seek to identify other dimensions along which experience might meaningfully vary.

Determining whether customer experience at the individual level is a complement to or substitute for the same at the organizational level also has meaningful implications for the management of outsourcing firms. Operationally, minimizing individual customer specificity is preferable because if individual workers must be dedicated to a customer, outsourcers lose flexibility in task allocation and face lower labor utilization. Dedicating particular staff to a small number of customers also might limit variety in the work of those individuals, which could lead to employee dissatisfaction and eventual turnover (Fried and Ferris 1987). Our findings suggest that, for new customers, an outsourcing firm may wish to keep individual providers relatively more focused on serving a specific customer. As organizational experience accrues with a specific customer, however, such dedication becomes less critical.

### 6.1. Limitations and Future Research

Despite the robustness of our results, our study faces several limitations. First, we cannot assume that our findings generalize to other settings. We note, however, that our results are likely relevant for a wide range of settings that are characterized by an individual performing a varied set of related and roughly repetitive activities for a range of customers. Similar contexts might include settings in manufacturing or professional services (e.g., software development, legal, or consulting services).

Second, despite our efforts to control for time-invariant factors such as individual talent and the “match” between individual providers and customers, our results may still be subject to concerns of bias due to remaining sources of endogeneity. Nonetheless, we reiterate that—within predefined bounds based on the range of technologies for which an individual has been trained and the hospitals at which an individual is able to practice—the assignment of individual cases does not

depend on the unobserved characteristics of cases, customers, or individual radiologists.

Third, the realities of our data require us to analyze individual and organizational experience differently. For individual experience, we are able to test for learning from customer experience as well as customer specificity. We examine the latter concept by including all types of experience for each radiologist in the model and testing whether customer–domain experience has a greater effect on learning than other types of experience. We find that this is the case. For organizational experience, our data only allow us to test whether learning occurs at the organizational level. Including a variable that captures all other OutsourceCo experience—which would be required to test for customer specificity at the organizational level—is not feasible as this variable is highly correlated with other experience variables in the model and would be akin to adding a variable for calendar time, which is already in our models. Future work should thus examine whether customer specificity also occurs at the organizational level. In addition, future work should explore the effect that other employees’ experiences with different customers has on an individual’s performance with a focal customer.

Fourth, though our study provides an accurate measurement of the number of interactions between an individual radiologist and a customer, we do not observe what takes place during each interaction. Future work should seek to examine how these interactions can be structured more effectively to improve coordination. For example, Huckman and Pisano (2006) find that an individual’s experience with the specific assets of his or her employer is important to improving performance (i.e., experience is firm-specific). They suggest that one source of this firm specificity may be the familiarity that emerges between workers within a given firm (Huckman et al. 2009, Staats 2012). Research that examines both how a radiologist interacts with a customer and how radiologists at a firm interact with each other could provide valuable additional insight.

Finally, our results only measure performance in terms of speed rather than clinical outcome or some other measure of performance quality. This is because our data reveal that only 0.3% of our cases are characterized by a quality “discrepancy” and that many of these discrepancies are simply the result of a need for clarification rather than deficient performance. This low level of quality problems is beneficial not only for patients but also for our empirical identification strategy. Specifically, to the extent that quality is almost uniformly acceptable across all providers in our sample, we are able to use read time as a measure of performance effectiveness. Future work should explore the effect of customer experience on quality. For example, outsourcing may lead to unexpected quality challenges, in some settings, as complex information must often be transmitted and translated across the boundaries of multiple organizations.

Although we expect that our results would hold with quality as a dependent variable, it is an important topic for further study.

Even with these potential limitations, our results have significant implications for both the suppliers and users of outsourced services. For firms that provide outsourced services, we emphasize that the observed nature of learning implies that staffing decisions should account for multiple dimensions of experience, such as prior experience with a specific customer, that are often overlooked in settings where activities are assumed to be “commoditized.” For firms that use outsourced services, our findings suggest that performance may be improved by efforts to leverage customer experience, particularly early in their relationship with an outsourcing firm. Such firms, however, should realize that just as such individual specificity improves performance, it also increases the potential for an outsourcer to “hold up” a customer that becomes reliant on the outsourcer’s expertise. Overall, our findings point to the need for future research that examines the long-term costs and benefits of leveraging the specific nature of experience.

## 6.2. Conclusion

Our study follows calls in the academy to go “behind” the learning curve (Adler and Clark 1991, Argote 1999, Lapré 2011). In particular, we are able to examine how experience accumulation across multiple levels in the firm affects individual performance (Hackman 2003) and, in so doing, make six contributions.

First, we study a type of experience—customer experience—that is both underexamined and of growing importance. Our setting not only provides us with detailed data to examine multiple interactions between providers and customers but also provides the “clean” assignment of tasks to individuals required for us to draw causal inferences from our results.

Second, we find evidence of customer specificity in *individual* performance. Further, our results also support the concept of domain specificity in healthcare. Given that not all experience has an equal impact on future performance, it is important to understand the incremental impact of these various types of experience on performance. Our results show that specialization in customer experience offers performance benefits for individuals. Future work should not only examine where experience comes from (e.g., customer) but also the heterogeneity of the knowledge gained within a particular type of experience (e.g., heterogeneity within a given customer; see Haunschild and Sullivan 2002).

Third, we find that *organizational* customer experience leads to improved individual performance. Because the work of an organization is conducted by individuals, it is important to identify the distinct impact of customer experience at each of these two levels. Our result at the organizational level also offers insight for research on strategic alliances. Prior work on learning in strategic

alliances emphasizes the need to learn about a partner to build a successful alliance (Doz 1996, Ariño and de la Torre 1998) and also highlights the possibility of knowledge transfer and learning *from* the alliance partner (see Inkpen and Tsang 2007 for a literature review). Though learning may be possible, it often requires significant effort on the part of both parties (Teece 1977, Inkpen and Pien 2006). Further, learning from other parties requires that the parties internalize their experience together to convert it into know-how (Simonin 1997). As noted by Inkpen and Tsang (2007, p. 504), the above stream of research has not directly examined repeated interactions between partners—the focus of our study.

Fourth, we find that increasing the variety of customer experience at the individual level may be related to faster customer-specific learning. Thus, we find that specialization and variety may be optimally used as mutually reinforcing rather than mutually exclusive strategies (Narayanan et al. 2009, Clark and Huckman 2012, KC and Staats 2012, Staats and Gino 2012). Fifth, our work speaks to a recent suggestion that “...[u]nderstanding when different types of experience are complements or substitutes for one other is an important topic for future research” (Argote and Miron-Spektor 2011, p. 1127). In examining customer experience, we find that individual and organizational customer experience are substitutes in terms of their effects on individual performance—greater organizational experience with a given customer reduces the importance of customer experience at the individual level. We recognize, however, that various circumstances (e.g., technology, work practices, structure, culture) might moderate the relationship between individual and organizational experience. Future work should seek to understand these factors and how they lead to either a complementary or a substitutive relationship.

Finally, our work offers guidance for both providers and customers in service settings. Namely, each should be cognizant of the detailed experience profiles of the individuals completing the work. Increasingly, managers looking to improve performance must focus on the portfolio of experiences gained not only by their employees but also by their service providers. Our hope is that unpacking experience along these lines will help build more accurate theory and generate additional insights for managers.

### Acknowledgments

The authors thank management at their field site for their commitment to this work. Frank Levy provided valuable feedback on an earlier draft of this paper. The authors are grateful to Linda Argote and three anonymous reviewers for helpful comments. All errors are the responsibility of the authors.

### Endnotes

<sup>1</sup>We emphasize that our use of the term “customer experience” refers to experience that a service provider (either an

individual or an organization) *gains with* a focal customer rather than experience that has been *accumulated by* that customer outside of its relationship with the service provider.

<sup>2</sup>For simplicity and clarity, in the remainder of the paper, we refer to an individual’s customer-domain experience and customer experience interchangeably.

<sup>3</sup>Medicare is the United States’ federal health insurance program for individuals 65 years and older and those falling into a small number of other specific categories.

<sup>4</sup>Some of the leading providers of outsourced teleradiology services are NightHawk Radiology, Teleradiology Solutions, and Virtual Radiologic. All of these companies have radiologists in the United States, and most also have radiologists based in other countries who are able to work during their standard business hours to interpret “off-hours” studies from the United States. For further discussion of these outsourced models, see Wachter (2006).

<sup>5</sup>Anatomical specialties observed in our data set include: abdomen, body, brain, breast, cardiovascular, chest, gastrointestinal/genitourinary, head and neck, musculoskeletal, obstetrics, spine, and other.

<sup>6</sup>Though this represents a substantial increase from the mean, it is well within the relevant range of customer-domain experience found in our data. The maximum number of reads in our data set that are customer- and domain-specific is 1,430. Moreover, this level of increase makes for a more meaningful comparison to other types of experience (e.g., *Indiv/Other-CustomerDomain*) for which mean levels are much higher (e.g., 7,579).

---

**Jonathan R. Clark** is an assistant professor of healthcare management in the department of health policy and administration at the Pennsylvania State University. He received his doctorate in health policy and management from Harvard University. His research addresses leadership and organization design issues in the healthcare industry, with a specific interest

in how the characteristics of organizations influence learning and performance.

**Robert S. Huckman** is a professor of business administration in the technology and operations management area at the Harvard Business School, where he also serves as the faculty co-chair of the school's Healthcare Initiative. He received his doctorate in business economics from Harvard University. His research focuses on the linkages between organizational characteristics and operating performance, with an emphasis on the healthcare industry.

**Bradley R. Staats** is an assistant professor in the operations area at the Kenan-Flagler Business School at the University of North Carolina at Chapel Hill. He received his doctorate from the Harvard Business School in technology and operations management. His research identifies key levers to improve knowledge-intensive service operations in a world of fragmenting work by building and testing empirical models.
